

# “The issue of IQ in internet-based early-warning systems for trend management”

Dr. Daniel Diemers

University of St. Gallen (HSG), Switzerland  
Institute of Sociology SfS

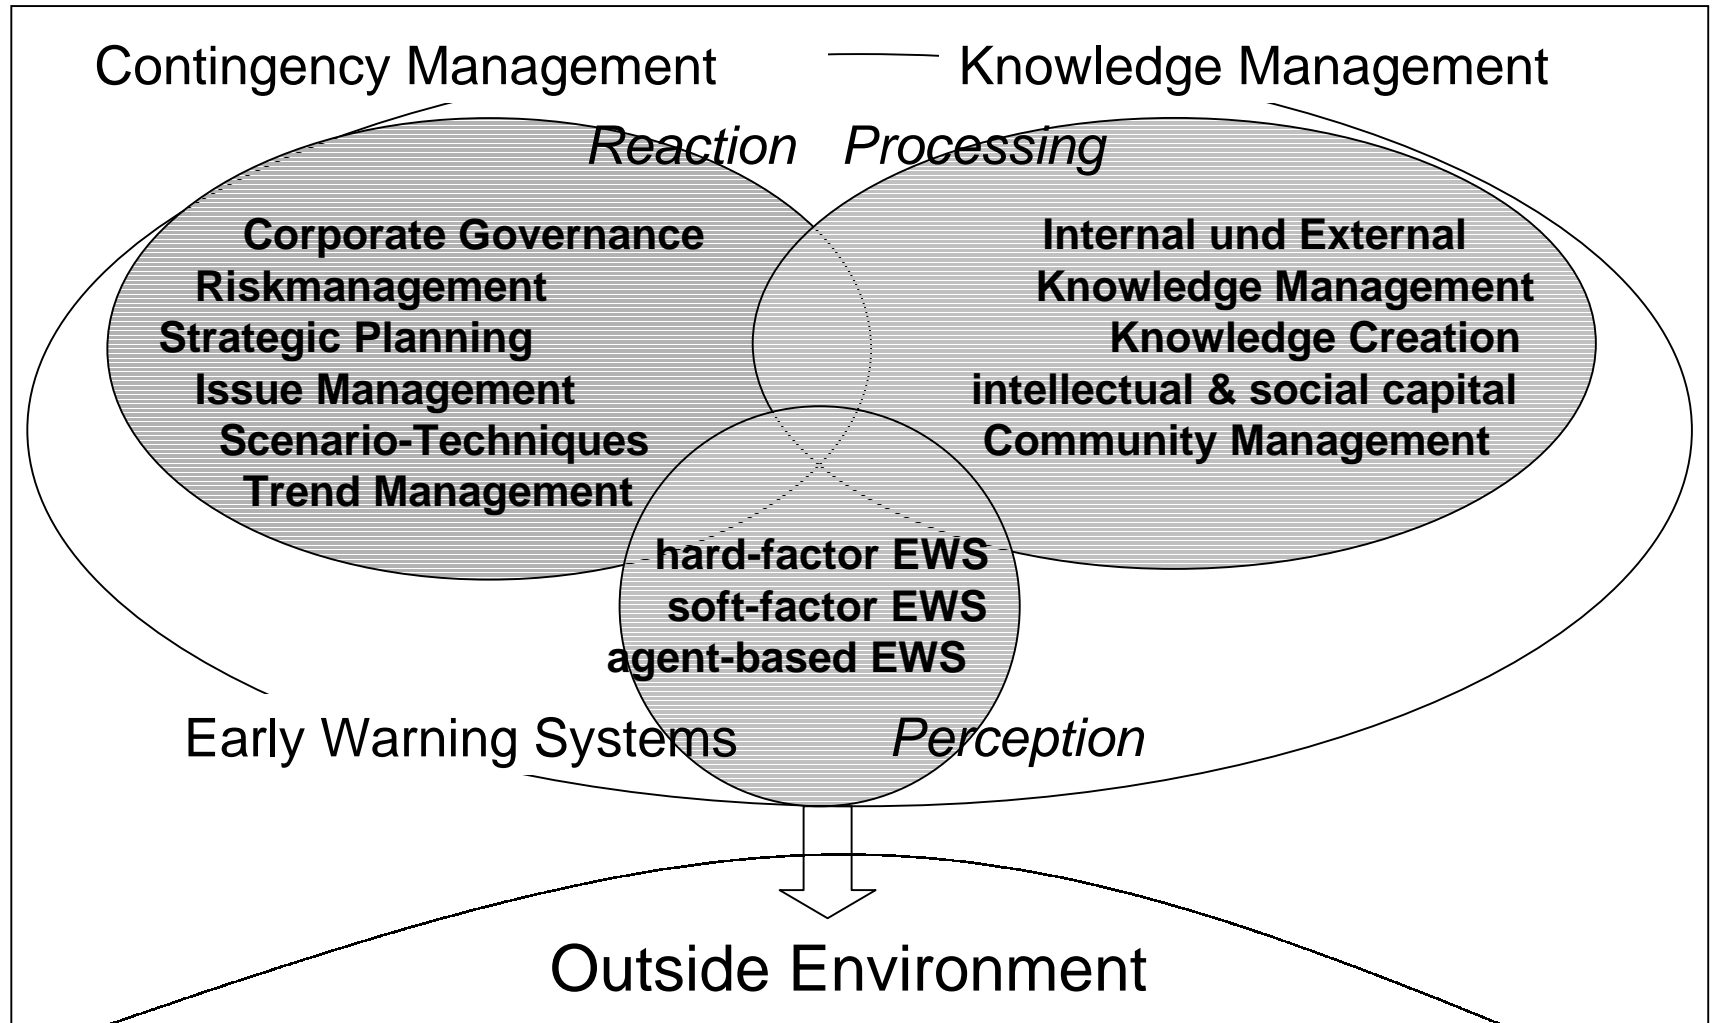

# Structure

1. Research Context: Trend Management
2. Internet-based Early Warning Systems
3. Our Framework for IQ
4. Practical Experiences with IQ issues
5. Conclusions and open questions

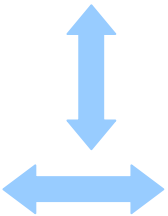

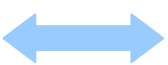

# 1. Research Context

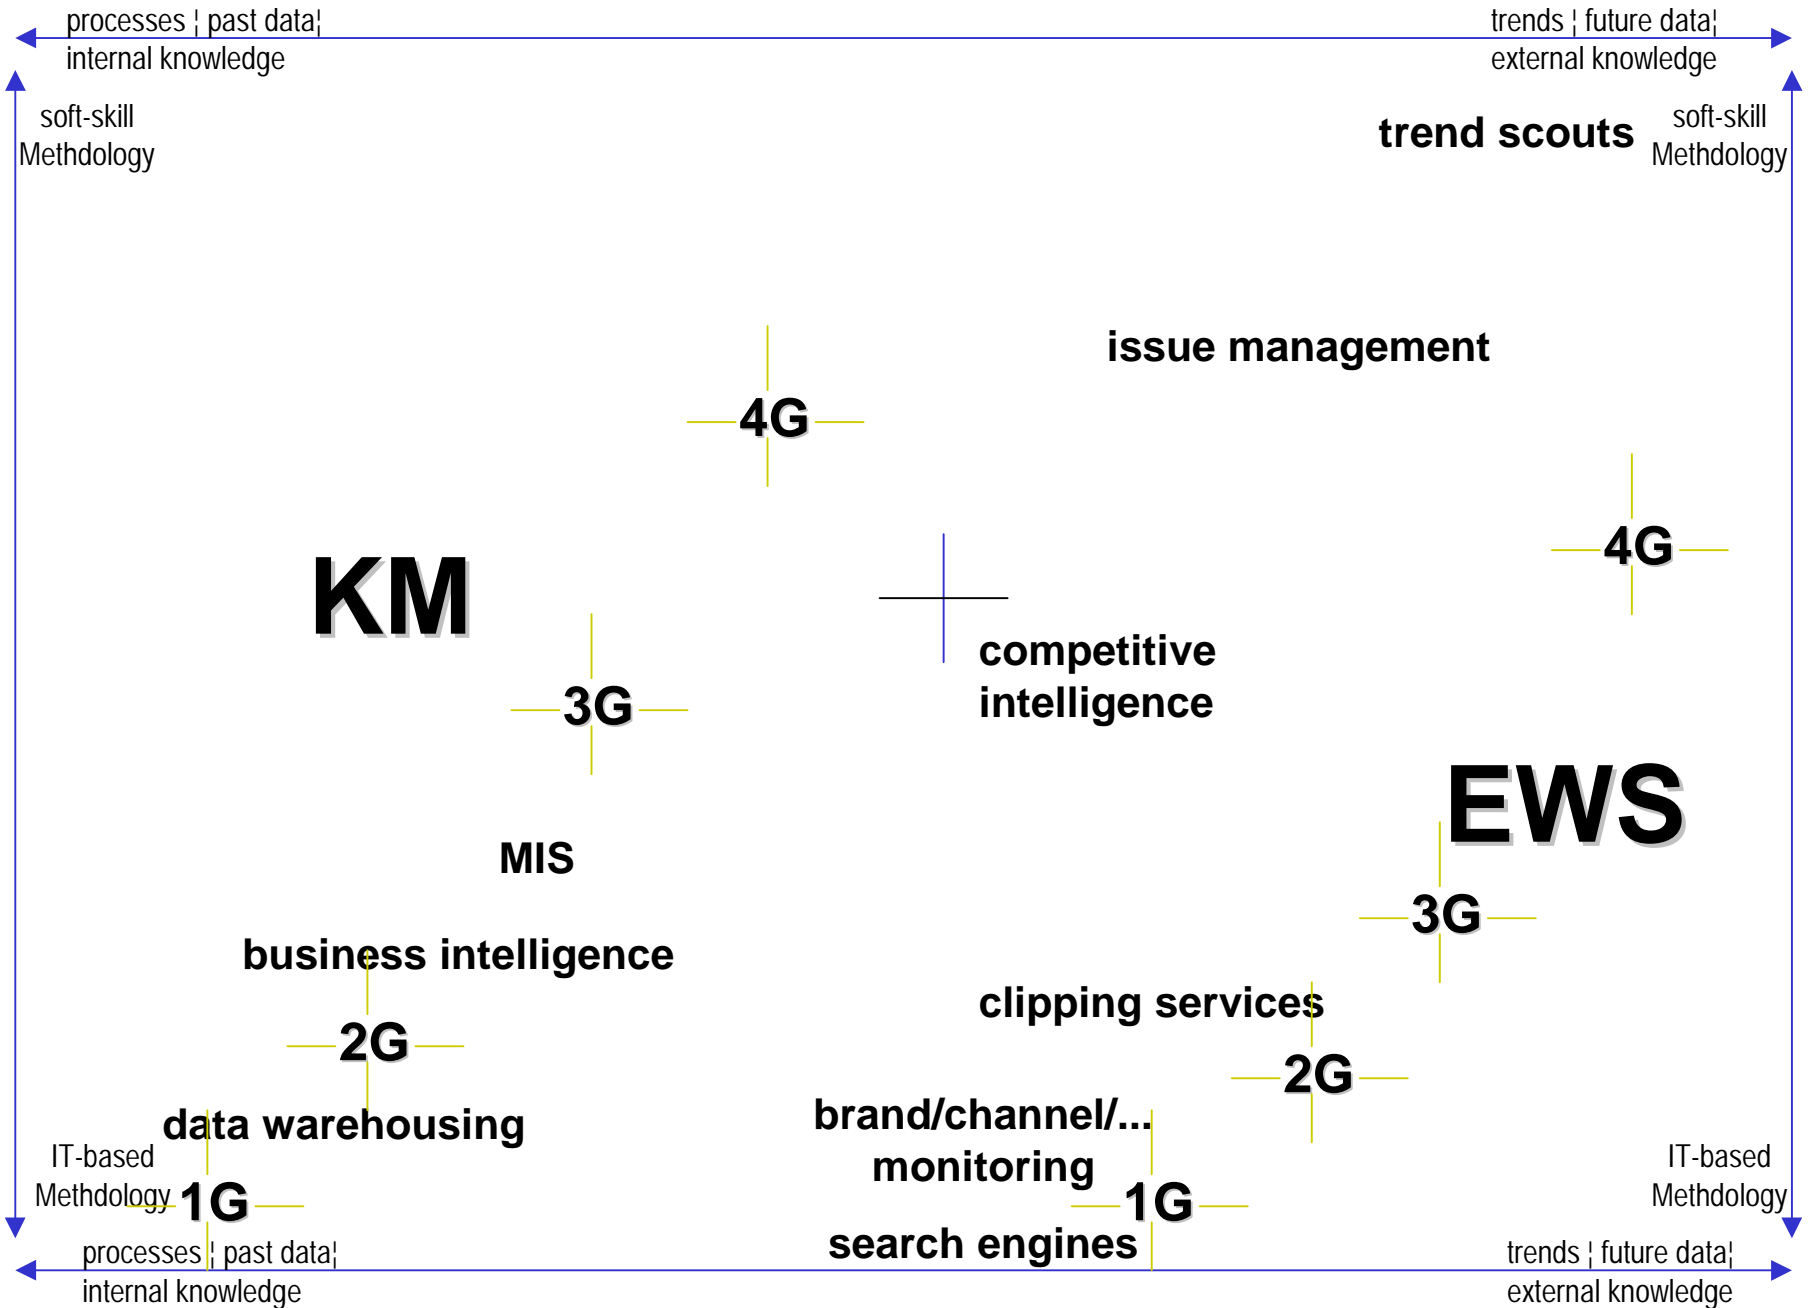

- Contingency Management, Knowledge Management, Early-Warning Systems
- Research Question:
  - „How can we measure and quantify the „quality“ of an identified Web source within an early-warning system?“

# Contingency Management (CM)

# Locating EWS in a CM Framework

- Internal view:
  - Knowledge Management, Data Mining, MIS, Business Intelligence
- External View:
  - Trend Scouts, Issue Management, Clipping Services, Monitoring Service, Search Engines
-  soft-skill vs. IT-based Methodology
-  future/external vs. past/internal data

## 2. Early Warning Systems

- Early Warning Systems shall help firms in their perception of the contingent corporate environment
- Early Warning Systems will play an increasingly important role in coping with the volatility and dynamics of markets

# a feasible EWS Methodology

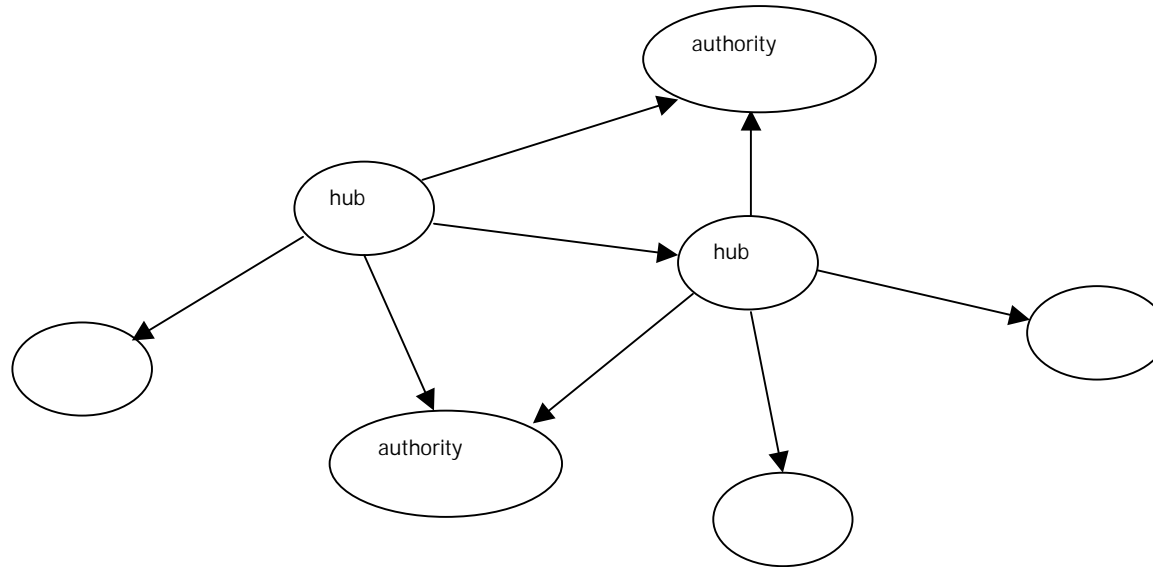

- 3 Phases:
  - Focused Crawling: Community Topography
  - Scanning/Monitoring/Analyzing
  - Border Control and Topography Updating

- 3 Modules:

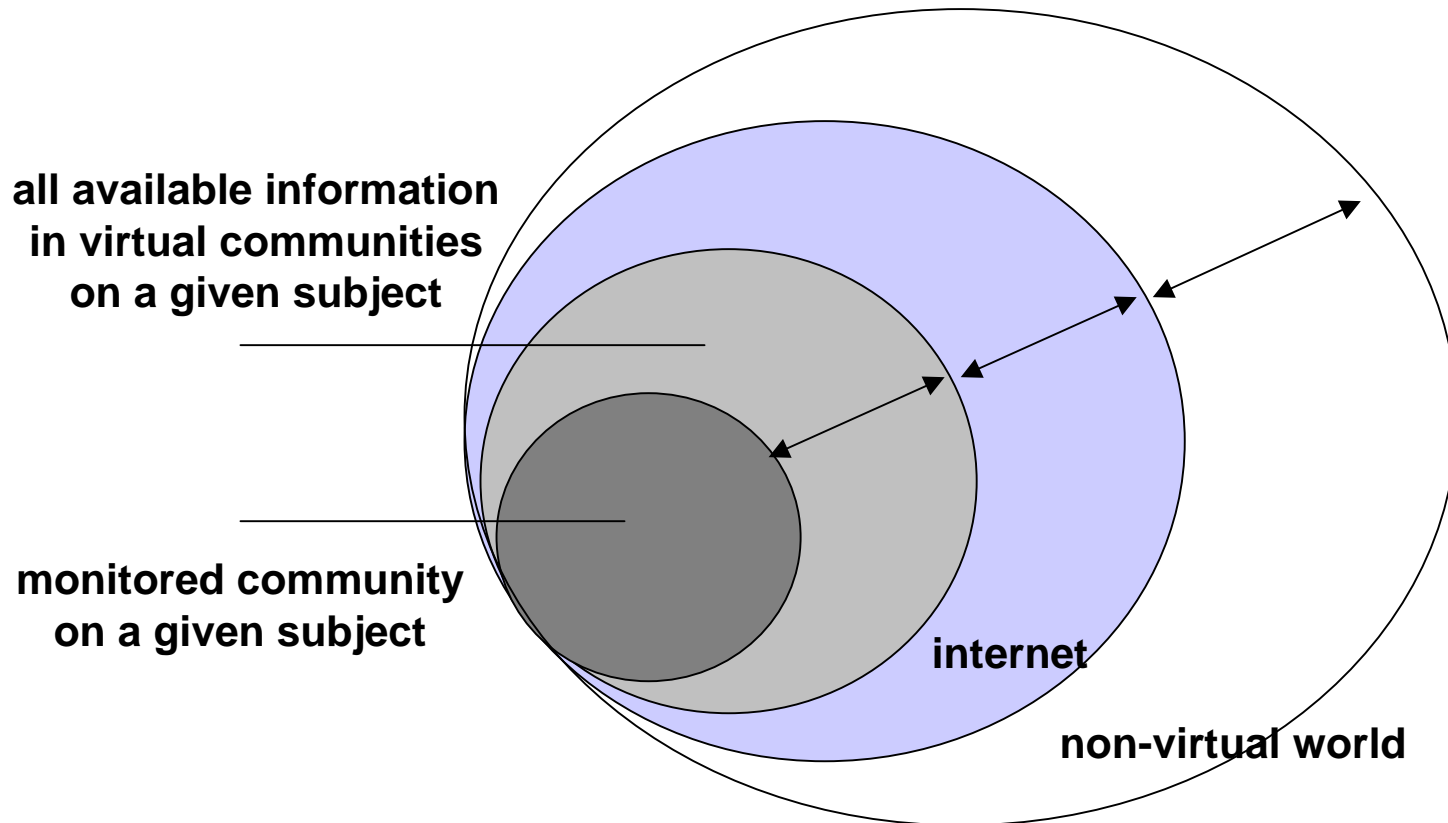

# The Community Perspective

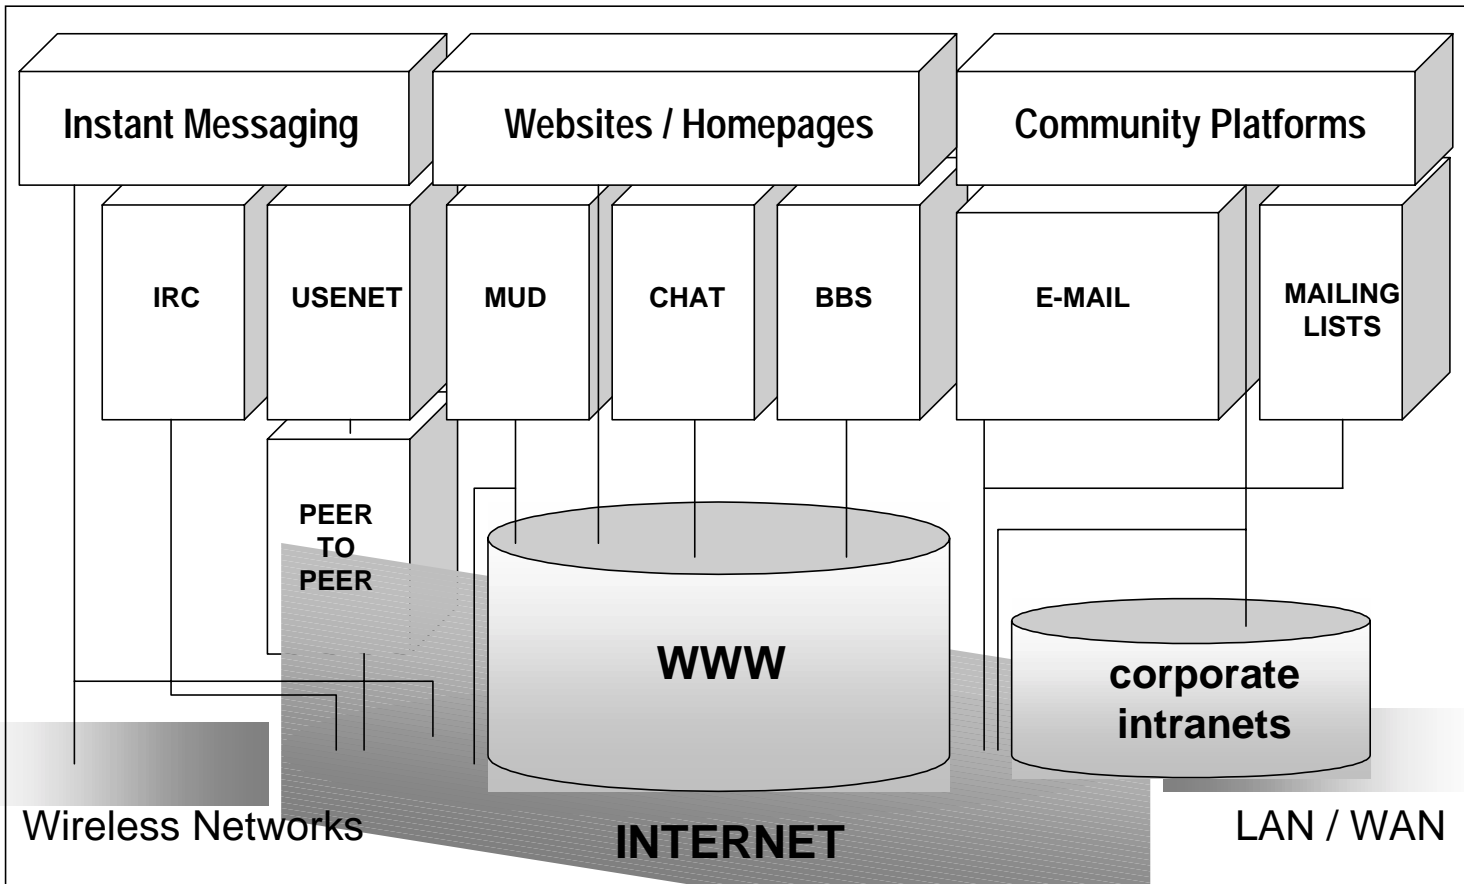

- **Diemers Theorem:** "only information that is referenced to or embedded in the respective community can develop any potential relevance".
- **Identify Hubs & Authorities within topical communities**

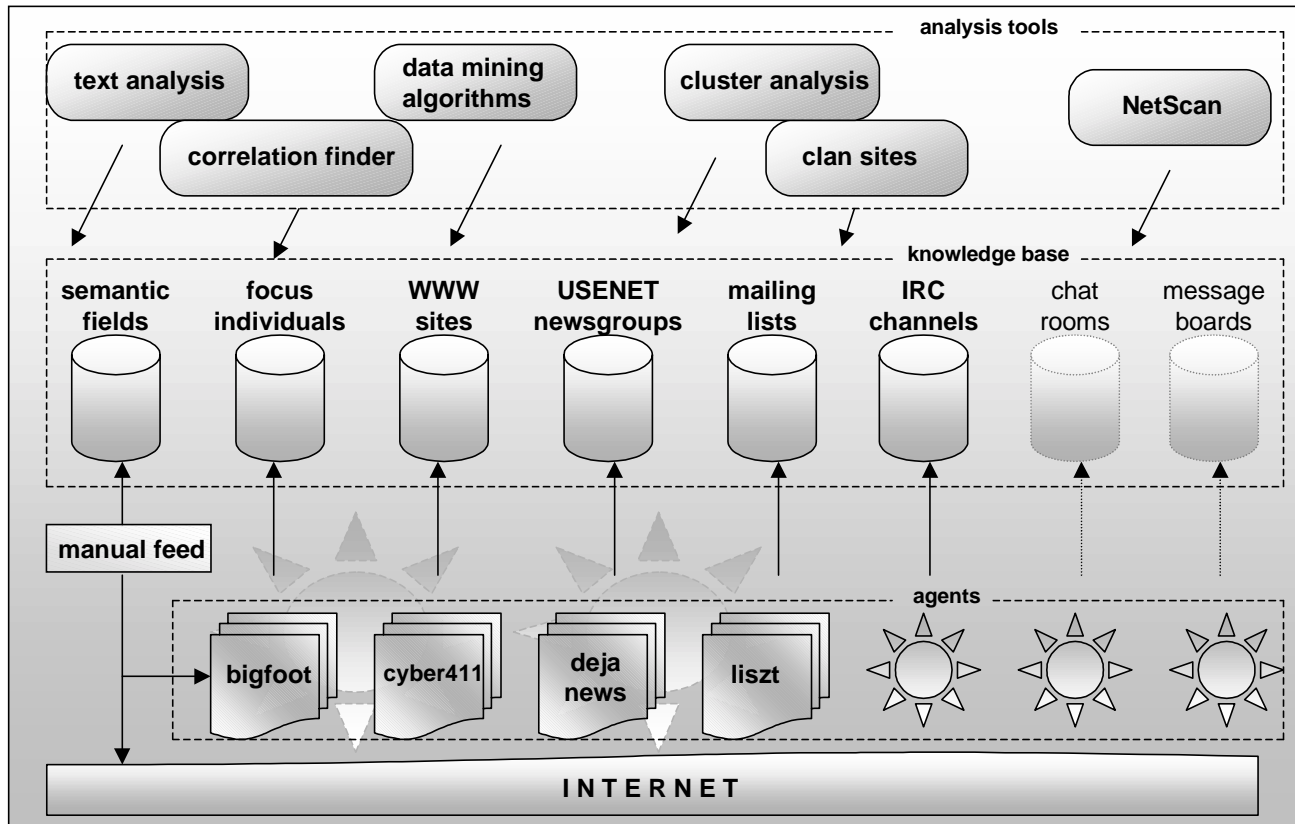

# Why Community Knowledge?

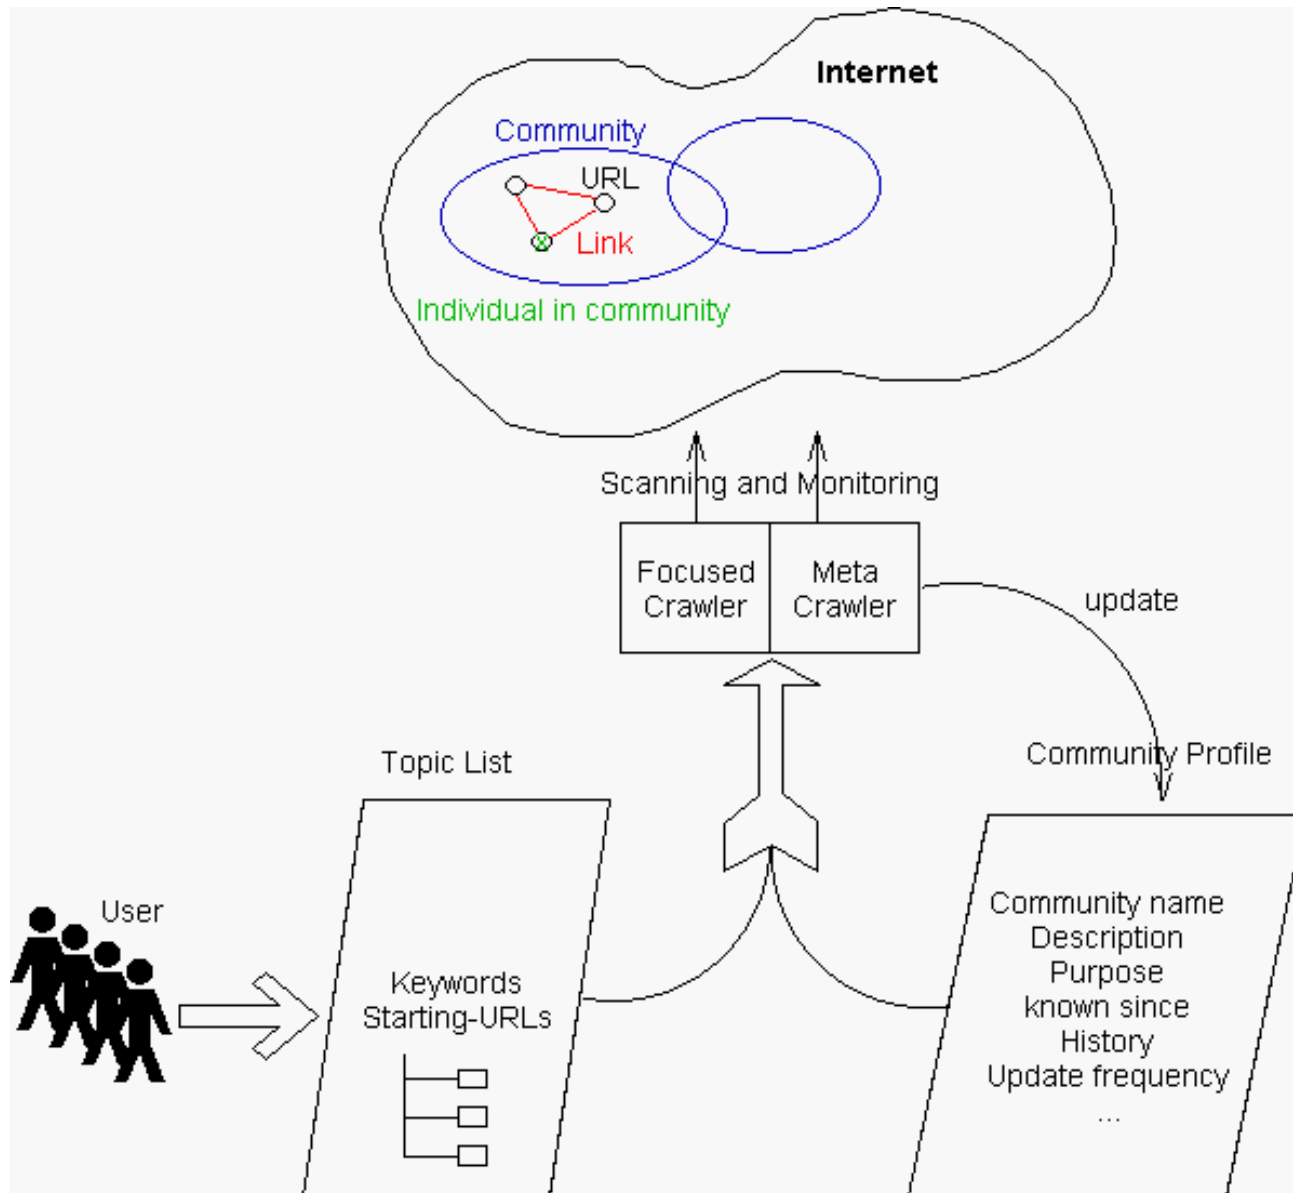

# Modelling Virtual Spaces

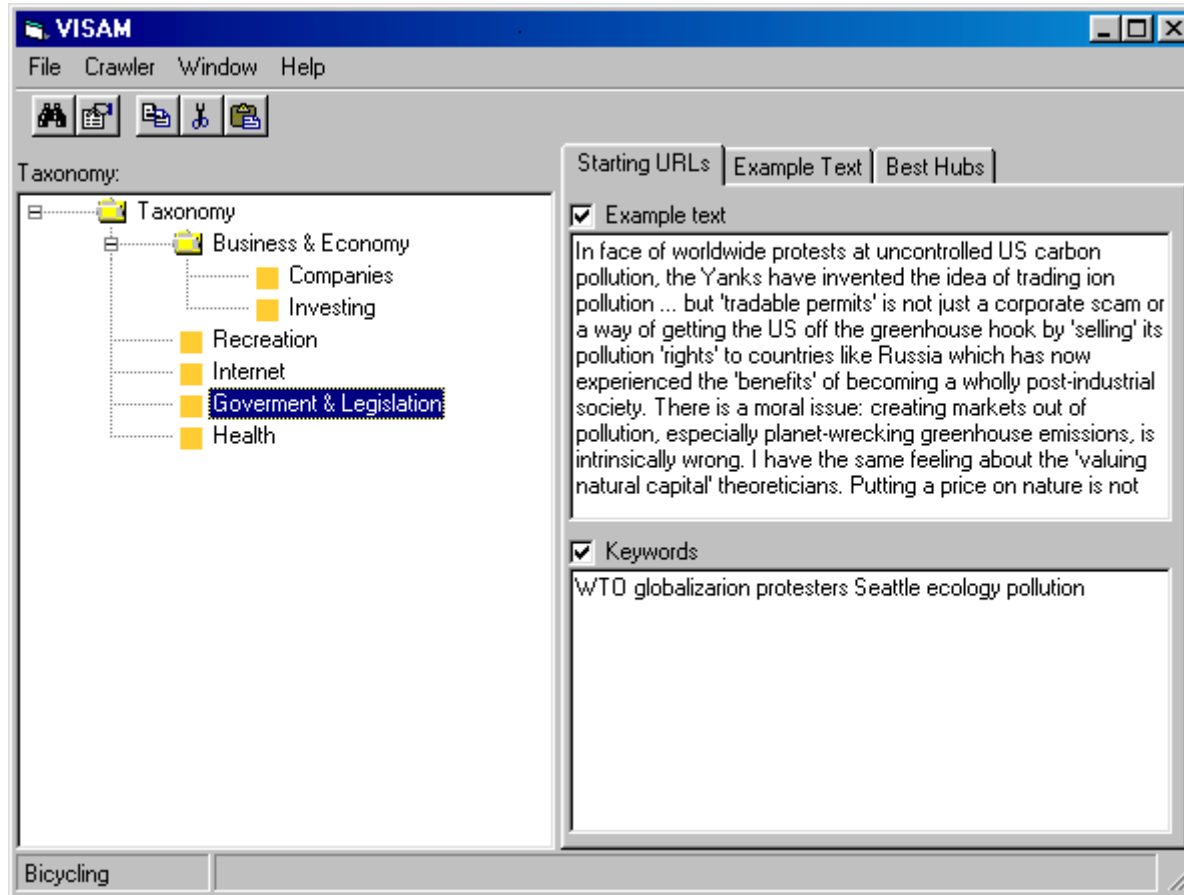

# Static Methodology Overview

# Dynamic Methodology Overview

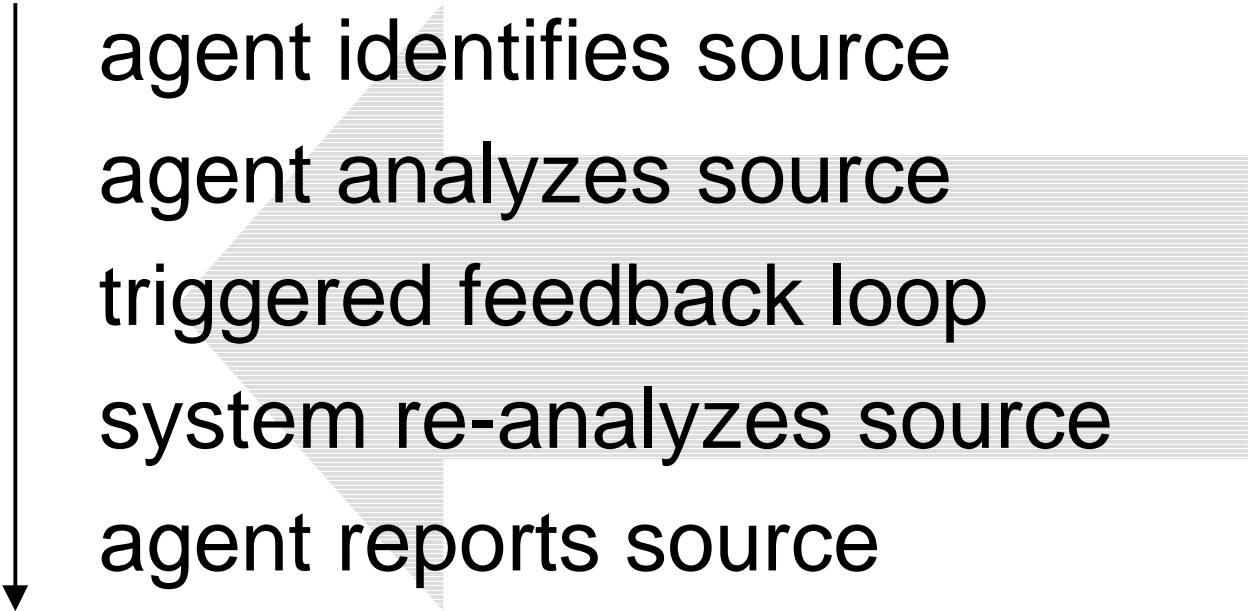

# Software GUI

# 3. Our Framework for IQ

- How can we measure and quantify the „quality“ of an identified Web source within an early-warning system?
- Agent-based IQ assessment process
- 3 levels of IQ criterias applied

# IQ Assessment Process

agent identifies source  
agent analyzes source  
triggered feedback loop  
system re-analyzes source  
agent reports source

IQ  
criterias

# 3 Levels of IQ Criterias

- General IQ Criteria (analysis)
- First Order Relevancy (semantic analysis)
- Second Order Relevancy (feedback loop)

**IQ Quantification Model**

# IQ Cat. I: General IQ Criteria

1 Latency (Agents sleep/frozen)	#seconds
2 Server Performance	#Kbits/s
3 Relative Size of Source	#Kbyte/Average
4 Age of Site	#days
5 Age of Last Update	#days
6 IP Address / Domain Name	semantic rating

# IQ Cat. II: First Order Relevancy

1 Keyword matches

#matches

→ RELEVANCY

analysis according to semantic networks with example text and keywords. Certain value triggers „second order analysis“

2 Number of Links

#links

→ HUB

number of links leaving site indicates hub quality

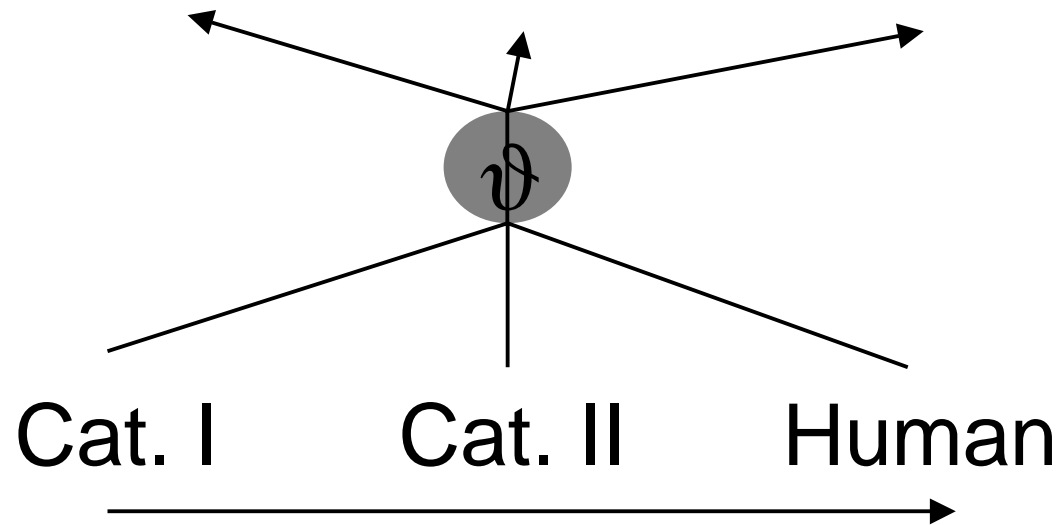

# Cat. III: Second Order Relevancy

- 1 Mentioning/Reference of Site #  
→ AUTHORITY
- 2 Number of inside links incoming #links  
→ AUTHORITY
- 3 Number of inside links outgoing #links  
→ HUB
- 4 Site already analyzed #days
- 5 Similarity of Site %
- 6 Reassessment of Relevancy semantic analysis

# IQ Quantification Model

Site „xy.net“:

REL [0.65] HUB [0.24] AUTH[0.67]

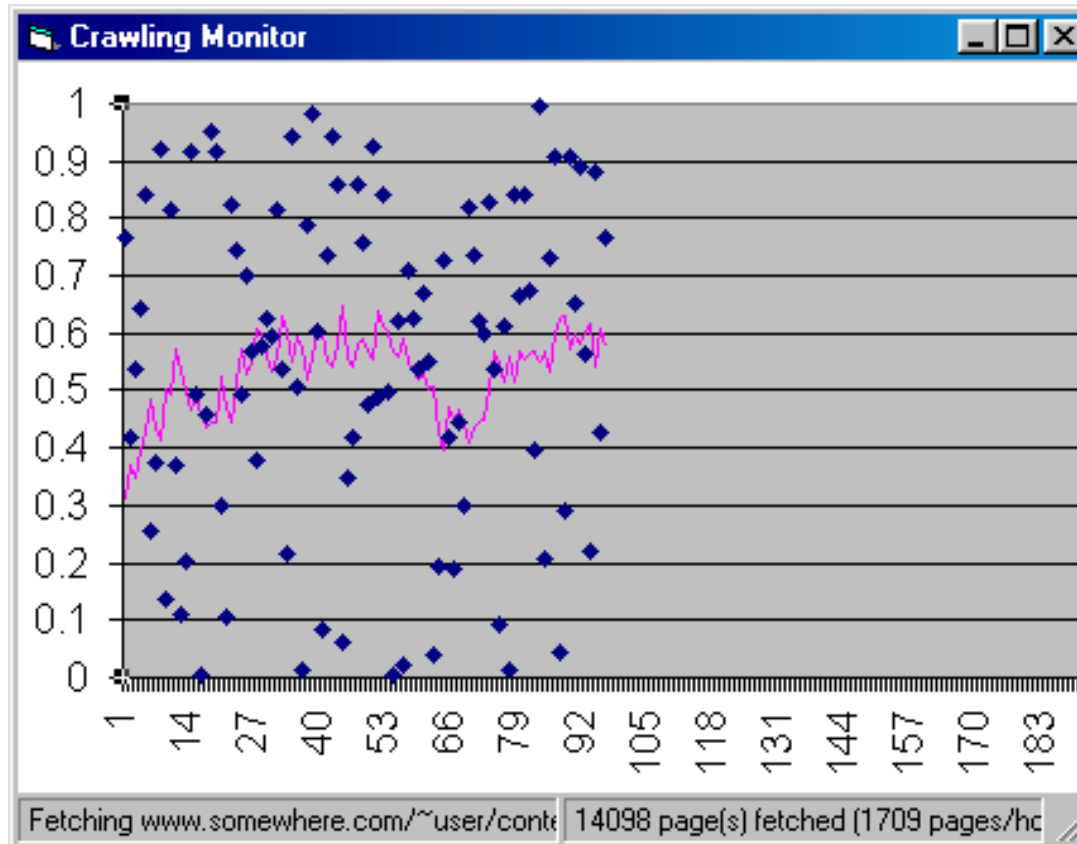

# Example:

## IQ Criteria I.6: IP/Domain Address

- Semantic analysis and rating
  - type of primary address and host:  
www.relevant.org\index.htm  
www.member.tripod.net\~john\xy.htm  
www.freenet.net\classof98page\xy.htm
  - domain name extensions  
.edu, .gov, .com, .biz, .net, .to, .li, ...etc.

# Example: Realtime IQ Measuring

# 4. Practical Experiences

- Achieving the right balance between Information Overload and Capturing all relevant Information
- Getting human IQ input into the early-warning system vs. automating the routine agent processes
- Applying high-quality semantic analysis (which theory/technique? which tools?)

# Practical Experiences (cont.)

- Establish a learning-system, especially in respect to IQ
- In Scanning Mode: achieve „minimum tolerance“, 90% „no blind-spots“ reliability
- In Monitoring Mode: achieve „zero tolerance“, 100% speed and reliability

# 5. Conclusions

- Internet-based early-warning systems are increasingly becoming accepted and useful tools for management
- monitoring and scanning virtual spaces requires highly sophisticated methodology and agent/software technology
- reliable results depend mainly on a sound and applicable framework for IQ

# IQ'2001 community!
